Abstract

This document formulates the logarithmic and exponential relationships between MIDI Note numbers $m \in [0, 127]$, fundamental frequencies $f \in \mathbb{R}^+$ (in Hz), microtonal cent tuning ratios, and Doppler frequency shifts under relativistic coordinate time dilation.

1 MIDI Note to Frequency Conversion ([mtof])

In 12-tone equal temperament (12-TET) with concert pitch reference $A_4 = 440$ Hz at MIDI Note $m = 69$, the fundamental frequency $f(m)$ is defined exponentially:

$$f(m) = 440 \cdot 2^{\frac{m-69}{12}} \quad (1)$$

For an arbitrary reference concert pitch $A_4 = f_0$:

$$f(m, f_0) = f_0 \cdot 2^{\frac{m-69}{12}} \quad (2)$$

2 Frequency to MIDI Note Conversion ([ftom])

The inverse mapping from fundamental frequency $f > 0$ to MIDI Note number $m(f)$ is derived by taking the base-2 logarithm:

$$m(f) = 69 + 12 \cdot \log_2 \left(\frac{f}{440} \right) \quad (3)$$

Using standard natural logarithms:

$$m(f) = 69 + \frac{12}{\ln 2} \cdot \ln \left(\frac{f}{440} \right) \quad (4)$$

3 Cent Tuning & Transposition Ratios

The frequency multiplier ratio $R(c)$ for a microtonal interval of c cents (100 cents = 1 semitone) is:

$$R(c) = 2^{\frac{c}{1200}} \quad (5)$$

Given a base frequency f_{base} and semitone shift Δm with fine detune cents c , the modulated frequency is:

$$f_{\text{final}} = f_{\text{base}} \cdot 2^{\frac{\Delta m + c/100}{12}} \quad (6)$$

4 Relativistic Doppler Pitch Shift under Time Warping

When an audio node is driven by a time dilation factor $\gamma(t)$, the apparent perceived playback frequency $f_{\text{perceived}}$ experiences an acoustic Doppler shift:

$$f_{\text{perceived}}(t) = f_{\text{base}} \cdot |\gamma(t)| \quad (7)$$

Under retrograde time flow ($\gamma(t) < 0$), the frequency magnitude remains $|f_{\text{perceived}}| = f_{\text{base}} \cdot |\gamma(t)|$ while the phase trajectories invert direction.
